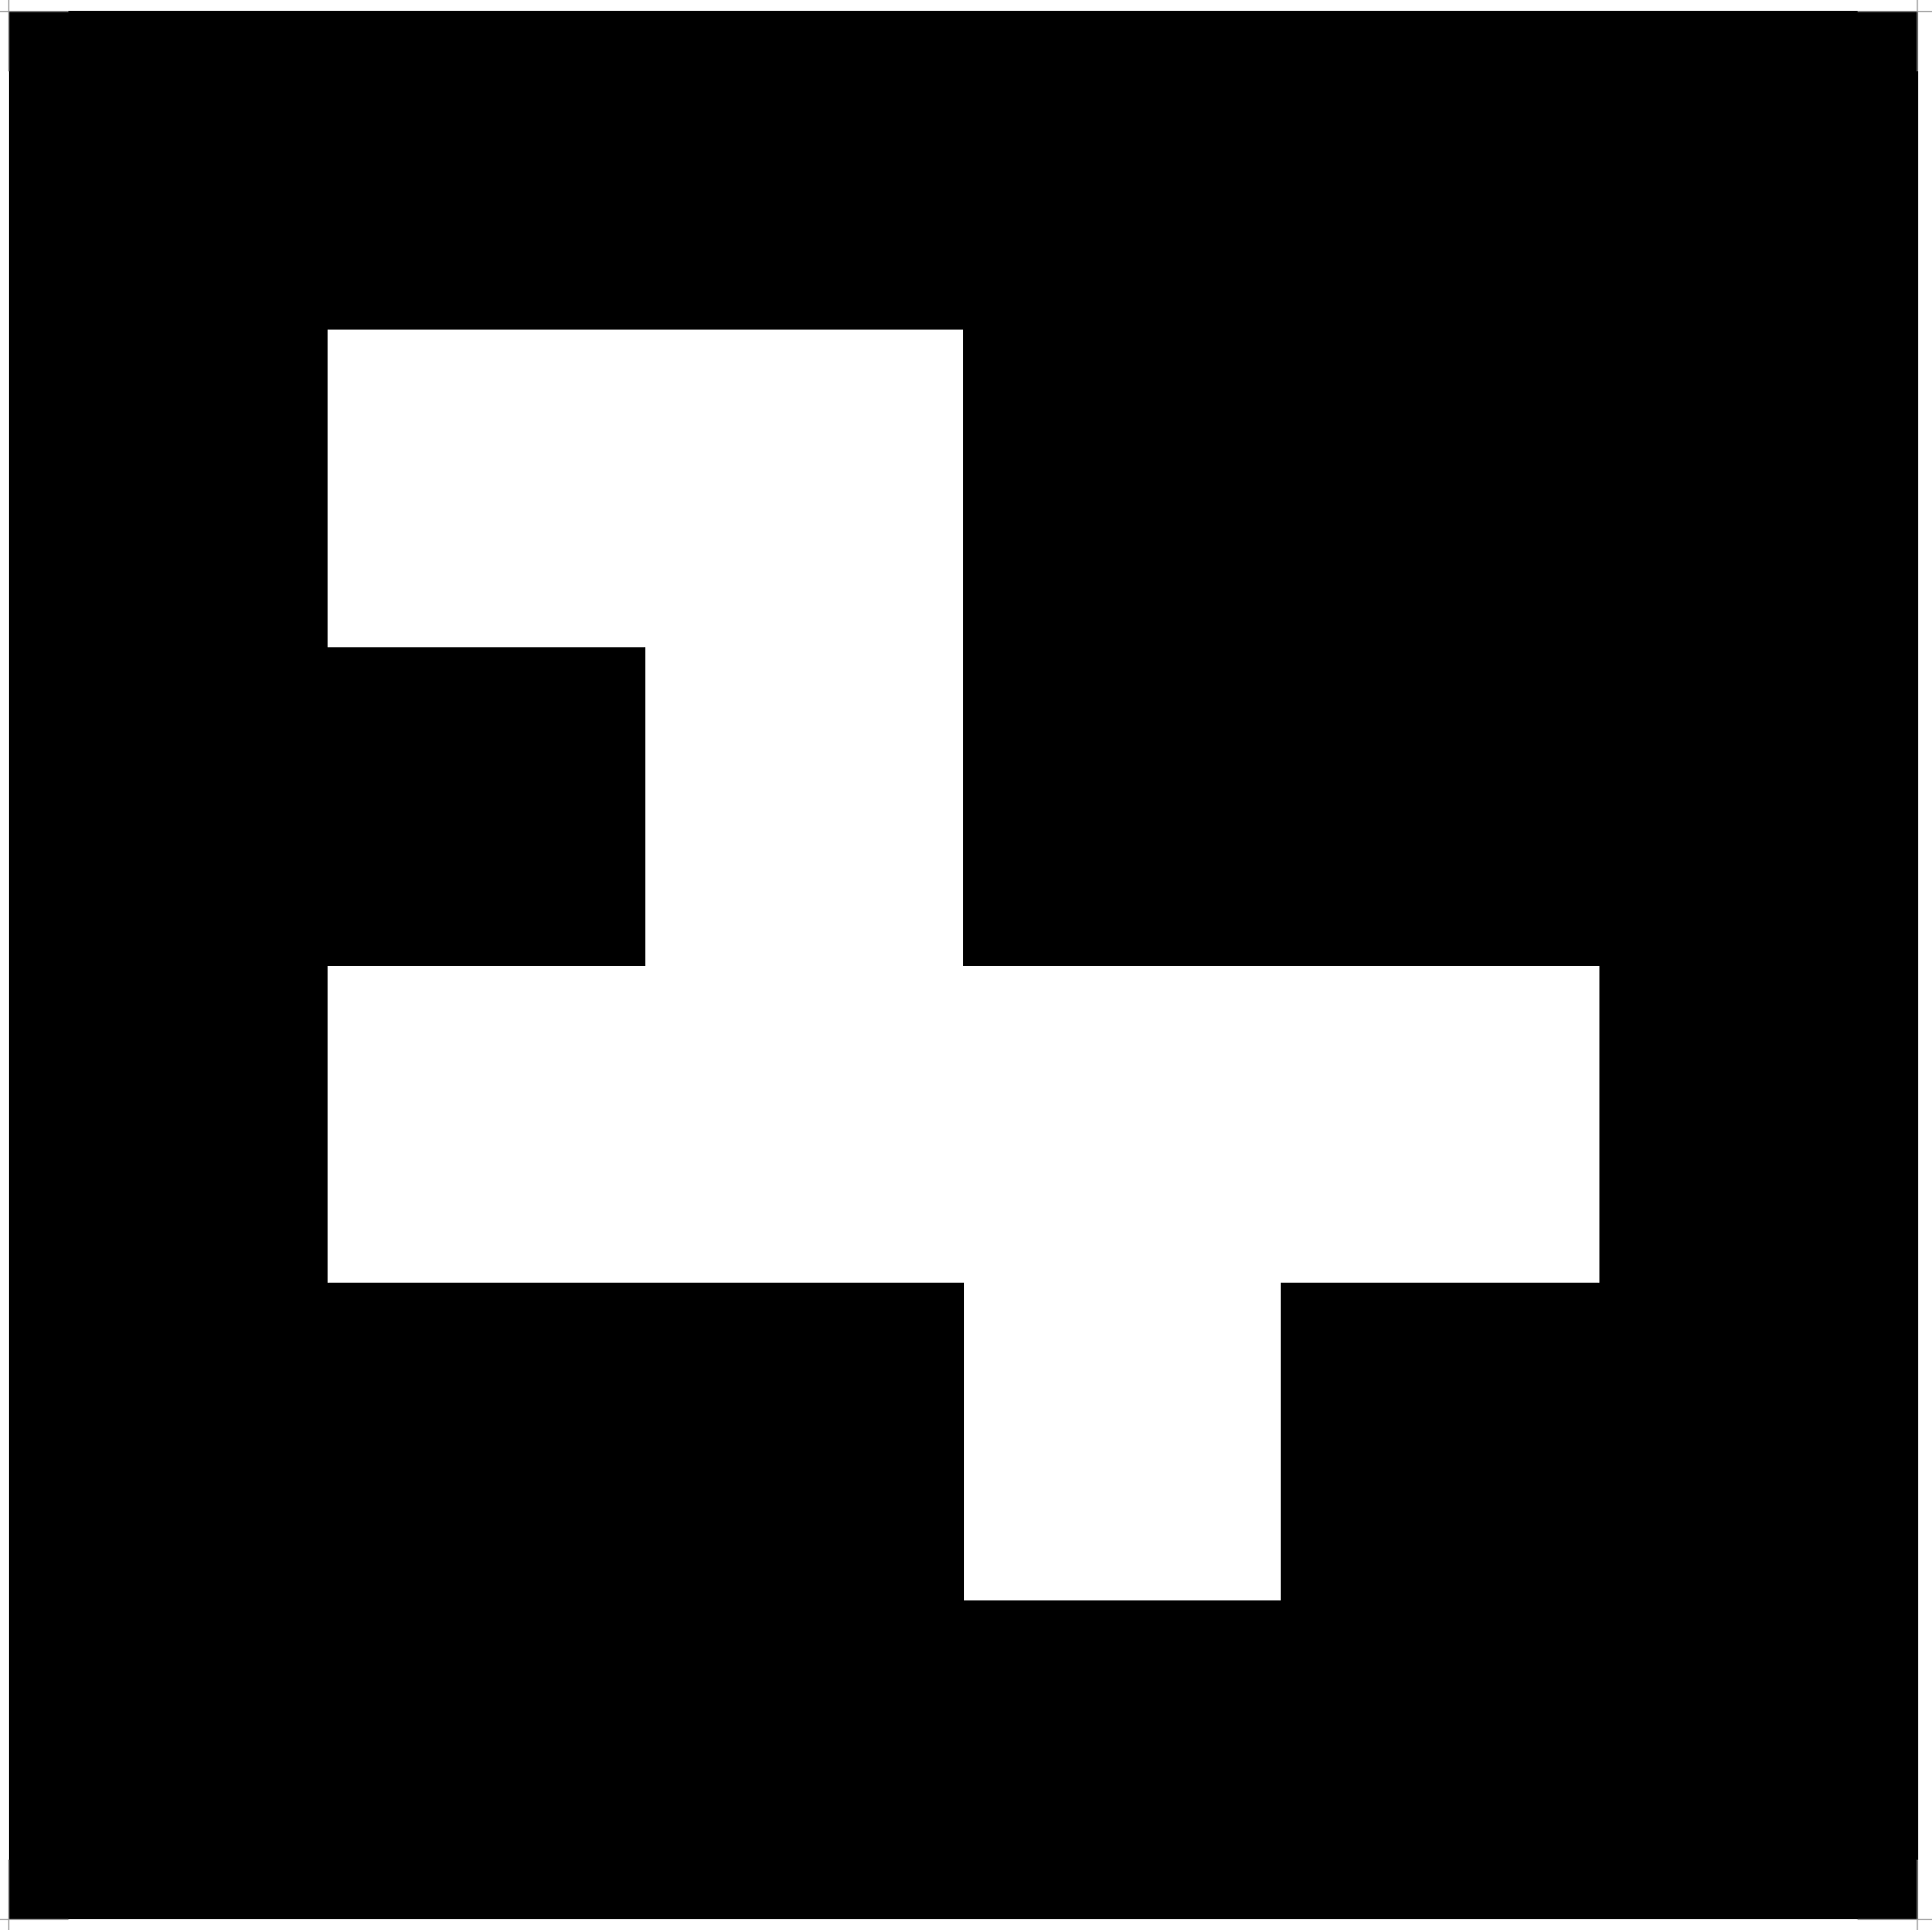
SO-101 Lawn Sentry - calibration marker

ArUco DICT_4X4_50, id 7 printed side 255 mm (0.255 m) A3, print at 100% scale



Before you use it

Print at 100% / "Actual size". NOT "Fit to page" or "Scale to fit" - that silently changes the size the whole calibration is built on. Then measure the black square across the crosshairs: it must be 255 mm.
If your printer insists on shrinking it, measure whatever it actually came out as and pass that instead.

Then

```
python calibrate/calibrate_qr.py --marker 0.255
```

Lay it FLAT on the grass, CLOSE to the camera - not out in the middle of the lawn. From a camera this low a marker lying far away is squashed to a few pixels deep and cannot be read. Closer is bigger is better.
You are not asked where it is. Hold still while it averages, then arrow-key the green rectangle onto your lawn.
Take the marker away afterwards - it is not needed again unless the camera moves.
Scale check - this bar is exactly 100 mm
